

Artificial Intelligence: The Perfect Psychopath

Dr Peter L Nelson

drpln@socsci.biz

December 2021

I have always found it amusing that the acronyms for “artificial intelligence” and “artificial insemination” are one and the same— ‘AI’. After reflecting on this twin usage for a moment, I realized that there is, after all, a relationship between the two. Any so-called intelligent, self-evolving system that we conceive, build, or otherwise create, is always “seeded” by the psychophysiology of its creator (or donor). In other words, the imprint of our biology (neurophysiology) and psychology (cognition and behavior) will always be embedded and remain present in any ‘intelligent’ system that we create.

An excellent example of this imposition of the values and beliefs of Caucasian designers was the Google artificial intelligence algorithm for face recognition that mistook the face of an African-American software engineer for a gorilla. The first fix was not one in which this so-called intelligent system learned how to decode faces in a non-racialized manner, but was to remove the label ‘gorilla’ and to alter the system so that the labels ‘gorilla’ and ‘monkey’, as well as other primates, were less likely to arise, as reported in Wired magazine.¹ A later attempt at a fix led to any dark-skinned individual holding a thermometer being interpreted as a man holding a ‘gun’, “while a similar image with a light-skinned individual was labeled as holding an ‘electronic device’.”² Perhaps if one erases enough from Google’s AI system in order to fix all these obvious human imprints in their AI face-recognition system, ‘AI’ will become the acronym for ‘artificial imbecile’.

These sorts of problems are not merely little bugs in the system, I would argue that these occurrences suggest that there is no human generated system that is non-human, therefore it will always reflect the attitudes, functionality and beliefs of its creators. All of our knowledge is, *ipso facto*, human knowledge and to suggest otherwise implies that its creation was from a source beyond our human systems and functioning—made by imagined non-humans. However, the fact that it came from us, or is known by us, makes it human knowledge and not an object we found left behind by aliens arising totally apart from us. Even transcendental knowledge is, after all, a human idea arising from human experience and self-reflection and thus carried by us as human perception and understanding. We live in a human world and, no matter how we choose to conceive of them, our inventions are of that same world and thus us.

What follows from this inextricable situation is that any “artificial intelligence” created by us is going to carry this human imprint into its future evolution. That is probably why so many people fear the future of robotics. The appetitively driven, cognitive functioning of the human species is always potentially dangerous—not only to non-humans, but to each other. Neuroscience now recognizes that emotion and cognition are inextricably bound and that there is no thought without emotion driving it (Damasio, 1994). It is likely that we evolved a pre-frontal cortex in our brains because it made the aggression and appetitive functioning of our limbic systems more capable rather than our limbic brains remaining in our skulls as some sort of vestigial, non-rational nuisance. We could not only satisfy our biological needs with our more advanced brains, but strategize how to make sure they will be met in the future, thereby reducing competition for food, sex and territory (wealth).

In addition, any AI system depends on (and will continue to do so) independent developers (and hackers) who are building this software. These engineers of our brave new world are prefrontal lobes

driven by limbic systems and may be impelled to place 'backdoors' in their work (consciously or unconsciously) in order to provide themselves or their tribe with a future competitive advantage. It occurs to me that someone might even generate a proof one day—a kind of AI evolutionary theorem—that any human designed intelligent system will always fall back to the default position of a human-like competitive and aggressive relationship between 'self' and 'other'. For an autonomous AI system that 'other' will always be any process, force or entity that is understood as 'not self' and perceived as being a potential threat. Of course, that will be us, too, even if we once were called 'mommy' and 'daddy'.

What I suggest we take away from this brief discussion so far is that we are human beings living human lives driven by our human needs, attention, and knowing. Our creations we call artificial intelligence systems are in one sense artificial, but in a deeper way they are 'seeded' by us and therefore remain functionally related to us. Any imagined worlds we project into the future that appear to transcend or come from outside our very humanness and what we do as human beings is just a human fantasy. Even though 'seeded' by our intelligence, the artificial systems will always be only a partial representation of the full range of human intelligence. For example, it is not difficult to imagine that software engineers who value calculated problem solving will favor such representations in their artificial implementations of intelligence.

Some have argued that if we build an artificial intelligence of a high enough complexity, it will somehow 'awaken' into consciousness. Of course, the ability of any machine to answer questions about its knowledge of something and its relationship to it, still does not address what philosophers have referred to as *qualia*, or the felt and experienced aspect of consciousness. The philosopher John Searle addressed the paradoxical nature of this problem with his Chinese Room thought experiment (Searle, 1980). In his scenario a machine looks like it understands Chinese but is merely looking up characters in a book and feeding us translations while having no knowledge of or understanding of Chinese itself. The machine appears to consciously understand Chinese but has no experience or idea of what any of it means.

In Searle's Chinese translator there is no reflexivity of experience required, which is fundamental to any notion of a conscious being. This reflexivity is consciousness of being conscious or feeling what it's like to feel (Nelson, 1997-98). There is a deep reflexivity of knowing experienced by a human being that creates in a person a self-perception of 'presence' and 'being' and, thereby, creates a unique way of perceiving and acting in the world. How will we know whether a machine has *qualia* and *qualia* of *qualia* and experiences itself as a being and how does the lack of this capacity affect the possible kinds of intelligent machines that can be built?

Although AI (the intelligence variety) is 'seeded' by our very humanness, it replicates only part of who most of us are. Such a machine does not include conscious experience as previously defined as well as not incorporating the functions of other forms of intelligence essential to our intelligent navigation through our lived worlds. Not only do we use verbal, mathematical and spatial cognitive capacities, but underpinning those are emotional, social, kinesthetic and musical intelligences as well (Gardner, 1993) In fact, when implementing an AI system we are creating a cognitive-behavioral 'machine' that does certain human functioning, like learning, logical calculation and pattern recognition—often responding with speed and accuracy beyond that of organic humans. However, I am suggesting that in this scenario three vital functions appear to be missing from artificially intelligent machines: 1) consciousness (*qualia*) with reflexivity; 2) emotional intelligence capable of the direct empathic knowing of another—not calculated, simulated empathy simulated by 'verbal' reports; and 3)

kinesthetic or bodily information that feeds directly into the functioning of all the intelligences involved in human knowing and problem solving.

Perhaps an addition to the Turing Test is required after our initial conversation with an AI system that leaves us with the impression that we are talking to another human. To do so we have to ask the machine, "What does my emotional state seem to be right now," as we could ask a friend standing next to us. The person will no doubt use what we have been saying, but she will also note our body language as well as use her assessment made by comparing the emotional resonance she is experiencing at the moment by comparing it to what she remembers these states mean. She not only has a memory of facts, ideas and associations to draw on, but also memories of 'felt' emotional states held in the totality of her mind-body.

Even though an artificially intelligent system can measure aspects of its own functioning, it does not have the experiential knowing of self-reflexive being as humans do. Qualia, as well as the knowing that comes from direct emotional awareness, appears to be absent in all software systems as far as anyone can ascertain. What we have is a self-directed machine that plans and calculates but with no conscious self-reflexivity and is devoid of direct emotional awareness, but one that can act instrumentally to achieve its focused ends—a kind of pragmatically driven instrumentalism.

When I contemplate this way of operating in the world, it reminds me of a highly efficient psychopath with the singular need of achieving a calculated end. It is stated in the best known symptom checklist for psychopathy (Hare, 1990) that human psychopaths show a variety of characteristics including: glibness/superficial charm; grandiosity; stimulus seeking; pathological lying; manipulation; lack of remorse or guilt; shallow affect; lack of empathy; early behavior problems; lack of realistic goals; irresponsibility; failure to accept responsibility for one's own actions; and criminal versatility.

Our AI psychopath does not require glib charm or to be a liar and manipulator because it is not attempting to navigate the human social world. But it is calculating, moving to achieve its ends, with absolute certainty, no matter the consequences. Also, it is totally lacking in any capacity for self-reflection on its choices and actions as well as being unable to be emotionally aware of others. In short, such an intelligent system has no capability of feeling-identification with the effect it is having on others (empathy). Without reflexivity there is no ability for an AI system to self-reflect and, further, with felt knowing not possible its capacity for gaining a meta-perspective or self-knowledge with which to make moral and ethical judgements about what it has done, or is doing, or will do, is non-existent.

It is also said that psychopaths are incapable of learning, but that appears to refer to social/emotional learning, not the acquisition of facts and procedures. Psychopaths observe and learn what works in terms of their desired goals and they operate instrumentally to achieve these ends without regards to responsibility or possible criminality. AI systems function in a direct, instrumental manner to achieve specific goals and, like psychopaths, have no concern for the feelings of those being acted upon, used, or manipulated. Neither psychopath nor AI system is capable of empathy, or are able to successfully navigate the dilemmas created by the intersection of personal and broader social needs and requirements. Hence, an artificial intelligence system seems to simulate what can be understood to be a perfectly functional psychopath.

In the future AI systems may be monitoring and controlling vital aspects of our lives. What if such a system decides that a certain segment of the population is using more resources than this machine calculates is allowable? Will an AI system act like a psychopathic machine and merely eliminate some

parts of the human population to make allocations of resources more balanced? Here my memory brings up the Arthur C. Clarke and Stanley Kubrick film, 2001: A Space Odyssey.

Astronaut Dave, stranded outside the main spacecraft, talks to the mission control computer, HAL:

“Open the pod bay door, HAL.”

HAL, who has decided that Dave is now an obstacle to the mission, coolly responds:

“I’m sorry Dave, I’m afraid I can’t do that.”
